Many scientists try to predict the future and decide upon what preventive measures to take in order to mitigate the spread of the Covid-19 infection. But what is R_0 and how do you estimate it? What about #flattenthecurve? How does the math behind all this work and what does the statistical models look like?

How do organization like the WHO and CDC do mathematical modelling to predict the growth of an epidemic? In this video we introduce the Susceptible-Infected-Recovered or SIR model. This is a simple system of differential equations that qualitatively behalves in a reasonable way. Studying this near the beginning gives a value called R_0 which governs the early growth rate which is exponential growth and is a standard metric in epidemiology. Indeed real world data shows the current epidemic is well modeled by this kind of exponential growth.

The two 2019 co-laureates of the Nobel Price in economics talk about the impact of COVID-19 on the economy.

Economist Thomas Piketty spoke exclusively to NDTV's Prannoy Roy on the economic repercussions of the coronavirus pandemic.
